Enumerating the total number of subtrees of trees*

Shuchao Li†, Shujing Wang

Faculty of Mathematics and Statistics, Central China Normal University, Wuhan 430079, P.R. China

Abstract: Over some types of trees with a given number of vertices, which trees minimize or maximize the total number of subtrees or leaf containing subtrees are studied. Here are some of the main results: (1) Sharp upper bound on the total number of subtrees (resp. leaf containing subtrees) among n-vertex trees with a given matching number is determined; as a consequence, the n-vertex tree with domination number γ maximizing the total number of subtrees (resp. leaf containing subtrees) is characterized. (2) Sharp lower bound on the total number of leaf containing subtrees among n-vertex trees with maximum degree at least Δ is determined; as a consequence the n-vertex tree with maximum degree at least Δ having a perfect matching minimizing the total number of subtrees (resp. leaf containing subtrees) is characterized. (3) Sharp upper (resp. lower) bound on the total number of leaf containing subtrees among the set of all n-vertex trees with k leaves (resp. the set of all n-vertex trees of diameter d) is determined.

Keywords: Subtrees; Leaves; Matching number; Domination number; Diameter;

AMS subject classification: 05C05, 05C10

1. Introduction

We consider only simple connected graphs (i.e. finite, undirected graphs without loops or multiple edges). Let $G = (V_G, E_G)$ be a graph with $u, v \in V_G$, $d_G(u)$ (or $d(u)$ for short) denotes the degree of u; the *distance* $d_G(u, v)$ is defined as the length of the shortest path between u and v in G; $D_G(v)$ (or $D(v)$ for short) denotes the sum of all distances from v. The *eccentricity* $\varepsilon(v)$ of a vertex v is the maximum distance from v to any other vertex. Vertices of minimum eccentricity form the *center* (see [1]). A tree T has exactly one or two adjacent center vertices. In what follows, if a tree has a bicenter, then our considerations apply to any of its center vertices.

A subset S of V_G is called a *dominating set* of G if for every vertex $v \in V_G \setminus S$, there exists a vertex $u \in S$ such that v is adjacent to u. A vertex in the dominating set is called a *dominating vertex*. For a dominating set S of graph G with $v \in S$ and $u \in V_G \setminus S$, if $vu \in E_G$, then u is said to be dominated by v. The *domination number* of graph G, denoted by $\gamma(G)$, is defined as the minimum cardinality of dominating sets of G. For a connected graph G of order n, Ore [9] obtained that $\gamma(G) \leqslant \frac{n}{2}$. And the equality case was characterized independently in [3, 20]. Given a graph G, the *matching number* of G is the cardinality of one of its maximum matchings.

Throughout the text we denote by P_n, $K_{1,n-1}$ the path and star on n vertices, respectively. $G - v$, $G - uv$ denote the graph obtained from G by deleting vertex $v \in V_G$, or edge $uv \in E_G$, respectively (this notation is naturally extended if more than one vertex or edge is deleted). Similarly, $G + uv$ is obtained from G by adding edge $uv \notin E_G$. For $v \in V_G$, let $N_G(v)$ (or $N(v)$ for short) denote the set of all the adjacent vertices of v in G. The *diameter* diam(G) of graph G is the maximum eccentricity of any vertex in G. We refer to vertices of

degree 1 of a tree T as *leaves* (or *pendants*), and the edges incident to leaves are called *pendant edges*. The unique path connecting two vertices v, u in T will be denoted by $P_T(v, u)$.

Let

$$W(T) = \frac{1}{2} \sum_{v \in V_T} D_T(v)$$

denote the *Wiener index* of T, which is the sum of distances of all unordered pairs of vertices. This topological index was introduced by Wiener [19], which has been one of the most widely used descriptors in quantitative structure-activity relationships. Since the majority of the chemical applications of the Wiener index deals with chemical compounds with acyclic molecular graphs, the Wiener index of trees has been extensively studied over the past years; see [1, 4, 5, 6, 10] and the references there for details.

Given a tree T, a *subtree* of T is just a connected induced subgraph of T. The number of subtrees as well the related subjects has been studied. Let T denote an n-vertex tree each of whose non-pendant vertices has degree at least three, Andrew and Wang [16] showed that the average number of vertices in the subtrees of T is at least $\frac{n}{2}$ and strictly less than $\frac{3n}{4}$. Székely and Wang [12] characterized the binary tree with n leaves that has the greatest number of subtrees. Kirk and Wang [7] identified the tree, given a size and maximum vertex degree, which has the greatest number of subtrees. Székely and Wang [15] gave a formula for the maximal number of subtrees a binary tree can possess over a given number of vertices. They also showed that caterpillar trees (trees containing a path such that each vertex not belonging to the path is adjacent to a vertex on the path) have the smallest number of subtrees among binary trees. Yan and Ye [22] characterized the tree with the diameter at least d, which has the maximum number of subtrees, and they characterized the tree with the maximum degree at least Δ, which has the minimum number of subtrees. Consider the collection of rooted labeled trees with n vertices, Song [11] derived a closed formula for the number of these trees in which the child of the root with the smallest label has a total of p descendants. He also derived a recurrence relation for the number of these trees with the property that for each non-terminal vertex v, the child of v with the smallest label has no descendants. The authors [8] here determined the maximum (resp. minimum) value of the total number of subtrees of trees among the set of all n-vertex trees with given number of leaves and characterize the extremal graphs. As well we determined the maximum (resp. minimum) value of the total number of subtrees of trees with a given bipartition, the corresponding extremal graphs are characterized. For some related results on the enumeration of subtrees of trees, the reader is referred to Székely and Wang [13, 14] and Wang [18].

It is well known that the Wiener index is maximized by the path and minimized by the star among general trees with the same number of vertices. It is interesting that the Wiener index and the total number of subtrees of a tree share exactly the same extremal structure (i.e. the tree that maximizes/minimizes the corresponding index) among trees with a given number of vertices and maximum degree, although the values of the indices are in no general functional correspondence. On the other hand, an acyclic molecule can be expressed by a tree in quantum chemistry (see [4]). Obviously, the number of subtrees of a tree can be regarded as a topological index. Hence, Yan and Ye [22] pointed out that to explore the role of the total number of subtrees in quantum chemistry is an interesting topic. As a continuance of those works in [7, 8, 12, 15, 16, 22] which studied the correlations between the Wiener index and the number of subtrees of trees, in this paper we continue to characterize the extremal tree among some types of trees which minimizes or maximizes the total number of subtrees. Through a similar approach, we also identify the extremal trees that maximize (minimize) the number of leaf containing subtrees.

2. Preliminaries

Given a tree T on n vertices. Let $\mathscr{S}(T)$ denote the set of subtrees of T. For two fixed vertices u, v in V_T, denote by $\mathscr{S}(T; u)$ (resp. $\mathscr{S}(T; u, v)$) the set of all subtrees of T, each of which contains u (resp. u and v). Let $\mathscr{S}^*(T)$ denote the set of all subtrees of T each of which contains at least one leaf in T. Given a vertex w in V_T, denote by $\mathscr{S}^*(T; w)$ the set of all subtrees of T each of which contains w and at least one leaf of T different from w. For convenience, we call the subtree that contains at least one *leaf of T leaf containing subtree.* Set $F(T) = |\mathscr{S}(T)|, f_T(v) = |\mathscr{S}(T; v)|, f_T(v_i * v_j) = |\mathscr{S}(T; v_i, v_j)|, F^*(T) = |\mathscr{S}^*(T)|, f^*_T(v) = |\mathscr{S}^*(T; v)|$. Let $PV(T)$ be the set of leaves of T; it is routine to check the following fact.

Fact 1. *Given a tree T, then $H(T) := T - PV(T)$ is a tree and $F^*(T) = F(T) - F(H)$.*

Lemma 2.1 ([15]). *Among trees on $n \geqslant 3$ vertices, the path P_n minimizes F^* with $F^*(P_n) = 2n - 1$; while the star $K_{1,n-1}$ maximizes F^* with $F^*(K_{1,n-1}) = 2^{n-1} + n - 2$.*

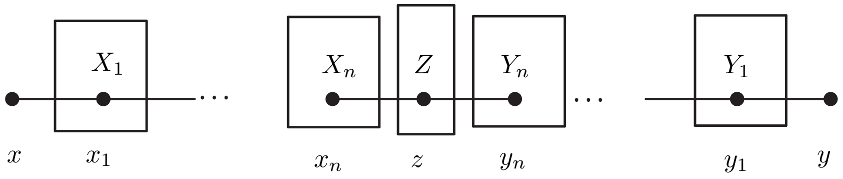

Figure 1: Path $P_W(x, y)$ connecting vertices x and y.

Consider the tree W in Fig. 1 with $x, y \in PV(W)$, and

$$P_W(x, y) = xx_1 \ldots x_n z y_n \ldots y_1 y (xx_1 \ldots x_n y_n \ldots y_1 y)$$

if $d_W(x, y)$ is even (odd) for any $n \geqslant 0$. After the deletion of all the edges of $P_W(x, y)$ from W, some connected components will remain. Let X_i denote the component that contains x_i, let Y_i denote the component that contains y_i, for $i = 1, 2, \ldots, n$, and let Z denote the component that contains z. (Note that z and Z exist if and only if $d_W(x, y)$ is even.)

Lemma 2.2 ([18]). *In the above situation, if $f_{X_i}(x_i) \geqslant f_{Y_i}(y_i)$ and $f^*_{X_i}(x_i) \geqslant f^*_{Y_i}(y_i)$ for $i = 1, \ldots, n$, then*

$$f_W(x) \geqslant f_W(y) \tag{2.1}$$

and

$$f^*_W(x) \geqslant f^*_W(y). \tag{2.2}$$

Furthermore, if a strict inequality $f_{X_i}(x_i) \geqslant f_{Y_i}(y_i)$ holds for any $i, i \in \{1, 2 \ldots, n\}$, then we have the strict inequalities in (2.1) and (2.2).

Lemma 2.3. *Let T' be a graph obtained from a tree T by deleting one leaf. Then $F(T') < F(T)$ and $F^*(T') < F^*(T)$. Furthermore, we have $f_{T'}(v) < f_T(v)$ and $f^*_{T'}(v) \leqslant f^*_T(v)$ for any vertex v in $V_{T'}$, with equality if and only if T is a path and v is the other leaf of T.*

Proof. It is straightforward to check that this result is true. We omit the procedure here. $\square$

If we have a tree T with x and y in V_T, and a rooted tree X that is not a single vertex, then we can build two new trees, first T', by identifying the root of X, u with x, second T'', by identifying the root of X, u with y (as depicted in Fig. 2).

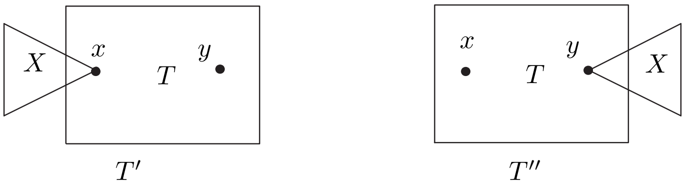

Figure 2: Trees T' and T''.

Lemma 2.4. *In the above situation, if $f_T(x) > f_T(y)$, then we have $F(T') > F(T'')$. Further more, if x is not a leaf of T and $f_T^*(x) \geqslant f_T^*(y)$, we have $F^*(T') > F^*(T'')$. And if both x and y are leaves of T and $f_T^*(x) \geqslant f_T^*(y)$, we also have $F^*(T') \geqslant F^*(T'')$, with equality if and only if both x and y are leaves of T, $f_T^*(x) = f_T^*(y)$ and X is a path with $d_X(u) = 1$.*

Proof. Note that

$$\begin{aligned} F(T') &= f_{T'}(x) + F(T'-x) = f_{T'}(x) + F(T-x) + F(X-u) \\ &= f_T(x)f_X(u) + (F(T) - f_T(x)) + (F(X) - f_X(u)), \\ F(T'') &= f_{T''}(y) + F(T''-y) = f_{T''}(y) + F(T-y) + F(X-u) \\ &= f_T(y)f_X(u) + (F(T) - f_T(y)) + (F(X) - f_X(u)). \end{aligned}$$

Hence,

$$F(T') - F(T'') = (f_T(x) - f_T(y))(f_X(u) - 1) > 0,$$

i.e., $F(T') > F(T'')$.

We partition the set $\mathscr{S}^*(T')$ of leaf containing subtrees of T' as follows:

$$\mathscr{S}^*(T') = \mathscr{S}_1^*(T') \cup \mathscr{S}_2^*(T') \cup \mathscr{S}_3^*(T'),$$

where

- $\mathscr{S}_1^*(T') = \{\hat{T} :\ \hat{T}$ is a subtree of T' with $x \in V_{\hat{T}}$ and $V_{T'} \cap (PV(T) \setminus \{x\}) \neq \emptyset.\ \}$.
- $\mathscr{S}_2^*(T') = \{\hat{T} :\ \hat{T}$ is a subtree of T' with $x \in V_{\hat{T}}$, $V_{T'} \cap (PV(T) \setminus \{x\}) = \emptyset$, $V_{T'} \cap (PV(X) \setminus \{u\}) \neq \emptyset\}$.
- $\mathscr{S}_3^*(T') = \{\hat{T} :\ \hat{T}$ is a subtree of T' with $x \notin V_{\hat{T}}$, $V_{T'} \cap PV(T') \neq \emptyset\ \}$.

Then we have

$$|\mathscr{S}_1^*(T')| = f_X(u) f_T^*(x), \quad |\mathscr{S}_2^*(T')| = f_X^*(u)(f_T(x) - f_T^*(x))$$

and

$$|\mathscr{S}_3^*(T')| = F^*(T-x) + F^*(X-u) = \begin{cases} F^*(T) - f_T(x) + F^*(X-u), & x \in PV(T), \\ F^*(T) - f_T^*(x) + F^*(X-u), & x \notin PV(T), \end{cases}$$

Hence,

$$F^*(T') = f_X(u)f_T^*(x) + f_X^*(u)(f_T(x) - f_T^*(x)) + \begin{cases} F^*(T) - f_T(x) + F^*(X-u), & x \in PV(T), \\ F^*(T) - f_T^*(x) + F^*(X-u), & x \notin PV(T), \end{cases} \tag{2.3}$$

Similarly,

$$F^*(T'') = f_X(u)f_T^*(y) + f_X^*(u)(f_T(y) - f_T^*(y)) + \begin{cases} F^*(T) - f_T(y) + F^*(X-u), & y \in PV(T), \\ F^*(T) - f_T^*(y) + F^*(X-u), & y \notin PV(T), \end{cases} \tag{2.4}$$

First consider that neither x nor y is a leaf of T, then (2.3) and (2.4) give

$$\begin{aligned} F^*(T') - F^*(T'') &= (f_T^*(x) - f_T^*(y))f_X(u) + f_X^*(u)(f_T(x) - f_T^*(x) - f_T(y) + f_T^*(y)) - f_T^*(x) + f_T^*(y) \\ &= (f_T^*(x) - f_T^*(y))(f_X(u) - f_X^*(u) - 1) + f_X^*(u)(f_T(x) - f_T(y)) > 0. \end{aligned}$$

Next consider y is a leaf while x is not a leaf of T, then in view of (2.3) and (2.4) we have

$$\begin{aligned} F^*(T') - F^*(T'') &= (f_T^*(x) - f_T^*(y))f_X(u) + f_X^*(u)(f_T(x) - f_T^*(x) - f_T(y) + f_T^*(y)) - f_T^*(x) + f_T(y) \\ &> (f_T^*(x) - f_T^*(y))f_X(u) + f_X^*(u)(f_T(x) - f_T^*(x) - f_T(y) + f_T^*(y)) - f_T^*(x) + f_T^*(y) \\ &= (f_T^*(x) - f_T^*(y))(f_X(u) - f_X^*(u) - 1) + f_X^*(u)(f_T(x) - f_T(y)) > 0. \end{aligned}$$

Now consider that both x and y are leaves of T, then (2.3) and (2.4) give

$$\begin{aligned} F^*(T') - F^*(T'') &= (f_T^*(x) - f_T^*(y))f_X(u) + f_X^*(u)(f_T(x) - f_T^*(x) - f_T(y) + f_T^*(y)) - f_T(x) + f_T(y) \\ &= (f_T^*(x) - f_T^*(y))(f_X(u) - f_X^*(u)) + (f_X^*(u) - 1)(f_T(x) - f_T(y)) \\ &\geqslant 0. \end{aligned} \tag{2.5}$$

Note that $f_X(u) > f_X^*(u)$ and $f_T(x) > f_T(y)$, hence the equality holds in (2.5) if and only if $f_T^*(x) = f_T^*(y)$ and $f_X^*(u) = 1$. Thus, $F^*(T') = F^*(T'')$ if and only if both x and y are leaves of T, $f_T^*(x) = f_T^*(y)$ and $f_X^*(u) = 1$ with X is a path and u is a pendant vertex of X. ☐

Lemma 2.5. *Given an n-vertex path $P_n = v_1v_2 \dots v_n$, one has*

(i) ([8]) $f_{P_n}(v_k) = f_{P_n}(v_{n-k+1}) = k(n-k+1), k \in \{1, 2, \dots, n\}$ *and* $f_{P_n}(v_1) < f_{P_n}(v_2) < \cdots < f_{P_n}(v_i) < f_{P_n}(v_{i+1}) < \cdots < f_{P_n}(v_{\lfloor \frac{n+1}{2} \rfloor}) = f_{P_n}(v_{\lceil \frac{n+1}{2} \rceil})$.

(ii) $f_{P_n}^*(v_1) = f_{P_n}^*(v_n) = 1, f_{P_n}^*(v_k) = n$ *for* $k \in \{2, \dots, n-1\}$.

Proof. (ii) follows directly by the the definition of $f_T^*(v)$. ☐

By Lemmas 2.4 and 2.5, the following lemma follows immediately.

Lemma 2.6. *Given a tree T with at least two vertices and a path $P_k = v_1v_2 \dots v_k$, let T_i be a tree obtained from T and P_k by identifying one vertex of T with v_i of P_k. Then* $F(T_i) = F(T_{k-i+1}), F^*(T_i) = F^*(T_{k-i+1})$, $F(T_1) < F(T_2) < \cdots < F(T_i) < \cdots < F(T_{\lfloor \frac{k+1}{2} \rfloor})$, *and* $F^*(T_1) < F^*(T_2) < \cdots < F^*(T_i) < \cdots < F^*(T_{\lfloor \frac{k+1}{2} \rfloor})$.

Lemma 2.7. *Given a tree T with $uv \in E_T$ and $d_T(u) = 1$, one has*

(i) ([8]) $f_T(u) \leqslant f_T(v)$ *with equality if and only if* $T \cong K_2$.

(ii) $f_T^*(u) \leqslant f_T^*(v)$ *with equality if and only if* $T \cong K_2$.

Proof. If $T \cong K_2$, it's routine to check that $f_T^*(u) = f_T^*(v) = 1$. In what follows, we consider that $T \ncong K_2$. Note that uv is a pendant edge, the map $f : \mathscr{S}^*(T, u) \to \mathscr{S}^*(T-u, v)$ that sends each T to $T-u$ is a bijection. On the other hand, by Lemma 2.3, we have $|\mathscr{S}^*(T-u, v)| < |\mathscr{S}^*(T, v)|$, i.e., $f_{T-u}^*(v) < f_T^*(v)$, hence our results follows immediately. ☐

3. Three transformations on trees

In this section, we introduce three transformations on trees, which will be used to prove our main results.

Definition 1. *Let T' (resp. T'') be a tree with $u \in V_{T'}$ (resp. $v \in V_{T''}$), where $|V_{T''}| = r + 1 \geqslant 2$. Let T_1 be a tree obtained from T' and T'' by identifying vertices u with v; see Fig 3. In particular, if $T'' \cong P_{r+1}$ with v being an endvertex, we may denote the resultant graph by T_2; see Fig 3. We say that T_2 is an A-transformation of T_1 on T''.*

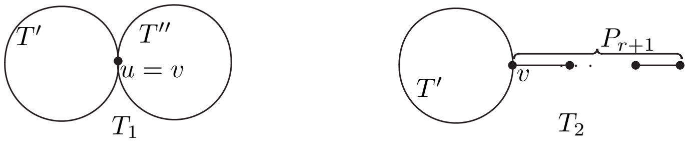

Figure 3: Trees T_1 and T_2.

Lemma 3.1. *Let T_1 and T_2 be the trees defined as above. Then*

(i) ([22]) *$F(T_1) \geqslant F(T_2)$ with equality if and only if $T'' = P_{r+1}$ with $d_{T''}(v) = 1$.*

(ii) *$F^*(T_1) \geqslant F^*(T_2)$ with equality if and only if $T'' = P_{r+1}$ with $d_{T''}(v) = 1$.*

Proof. In view of the proof of Lemma 2.4, let T' be X and T'' (resp. P_{r+1}) be T in Lemma 2.4. Then we have

$$\begin{aligned}
F^*(T_2) =& f_{T'}(u) f^*_{P_{r+1}}(v) - f^*_{T'}(u)(f_{P_{r+1}}(v) - f^*_{P_{r+1}}(v)) + F^*(P_{r+1}) - f_{P_{r+1}}(v) + F^*(T' - u) \\
=& (f_{T'}(u) - f^*_{T'}(u)) + (f^*_{T'}(u) - 1)(r + 1) + F^*(P_{r+1}) + F^*(T' - u), \qquad (3.1) \\
F^*(T_1) =& f_{T'}(u) f^*_{T''}(v) + f^*_{T'}(u)(f_{T''}(v) - f^*_{T''}(v)) + \begin{cases} F^*(T'') - f_{T''}(v) + F^*(T' - u) & v \in PV(T''), \\ F^*(T'') - f^*_{T''}(v) + F^*(T' - u) & v \notin PV(T'') \end{cases} \\
=& (f_{T'}(u) - f^*_{T'}(u)) f^*_{T''}(v) + f^*_{T'}(u) f_{T''}(v) + \begin{cases} F^*(T'') - f_{T''}(v) + F^*(T' - u) & v \in PV(T''), \\ F^*(T'') - f^*_{T''}(v) + F^*(T' - u) & v \notin PV(T'') \end{cases} \\
\geqslant& (f_{T'}(u) - f^*_{T'}(u)) f^*_{T''}(v) + (f^*_{T'}(u) - 1) f_{T''}(v) + F^*(T'') + F^*(T' - u) \qquad (3.2) \\
\geqslant& (f_{T'}(u) - f^*_{T'}(u)) + (f^*_{T'}(u) - 1) f_{T''}(v) + F^*(T'') + F^*(T' - u) \qquad (3.3) \\
\geqslant& (f_{T'}(u) - f^*_{T'}(u)) + (f^*_{T'}(u) - 1)(r + 1) + F^*(P_{r+1}) + F^*(T' - u) \qquad (3.4) \\
=& F^*(T_2).
\end{aligned}$$

Equality holds in (3.2) if and only if v is a leaf of T''. Note that $f_{T'}(u) > f^*_{T'}(u)$, hence equality holds in (3.3) if and only if $f^*_{T''}(v) = 1$, i.e., v is a leaf of a path; Equality holds in (3.4) if and only if $T'' \cong P_{r+1}$ and v is a leaf. The last equality follows by (3.1). Hence, $F^*(T_1) = F^*(T_2)$ if and only if $T'' = P_{r+1}$ and v is one of its endvertices, as desired. □

Definition 2. *Let T_1 be the graph as depicted in Fig. 4, where T' (resp. T'') is a tree with at least two vertices. Let $\hat{T}_2$ be a tree obtained from T_1 by deleting the edge uv and identifying its endvertices. Let T_2 be the tree obtained from $\hat{T}_2$ by attaching an pendant edge to u; see Fig. 4. We call the procedure constructing T_2 from T_1 the B-transformation of T_1.*

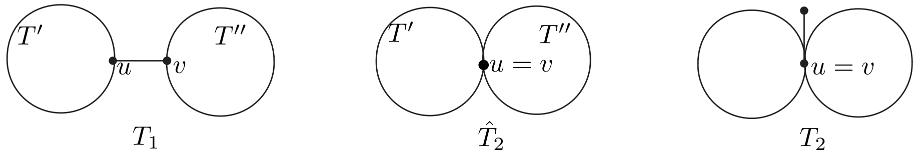

Figure 4: Trees $T_1, \hat{T}_2$ and T_2.

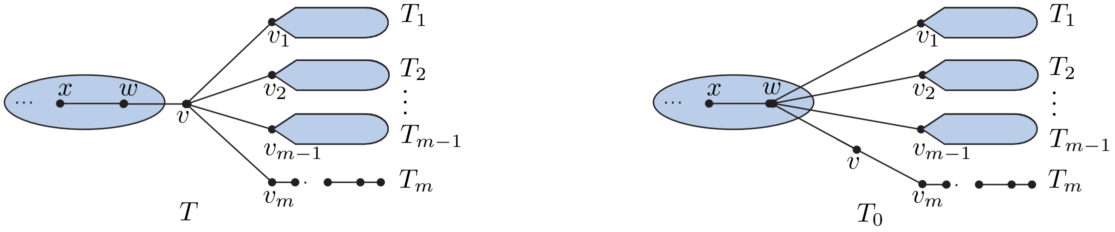

Figure 5: C-transformation on v.

By Lemmas 2.4 and 2.7, the following lemma follows immediately.

Lemma 3.2. *Let T_1 and T_2 be the trees defined as above, we have $F(T_1) < F(T_2)$ and $F^*(T_1) < F^*(T_2)$.*

Definition 3. *Let T be an arbitrary tree, rooted at a center vertex u and let v be a vertex with degree $m+1$. Suppose that $wv \in E_T$ and $P_T(u,w) \subset P_T(u,v)$(we call w the parent of v in T) and that $T_1, T_2, \dots, T_m$ are subtrees under v with root vertices $v_1, v_2, \dots v_m$, such that the tree T_m is actually a path. We form a tree T_0 by removing the edges $vv_1, vv_2, \dots vv_{m-1}$ from T and adding new edges $wv_1, wv_2, \dots wv_{m-1}$; see Fig. 5. If v is not a center vertex, we say that T_0 is a C-transformation of T. And if w and v are both center of T with $d_T(w) > 2$, we say that T_0 is a C'-transformation of T.*

This transformation preserves the number of pendant vertices in a tree T, and does not increase its diameter.

Lemma 3.3. *Let T and T_0 be the trees defined as above, we have $F(T) < F(T_0)$ and $F^*(T) < F^*(T_0)$.*

Proof. Let W be the component that contains v in $T - \{vv_1, vv_2, \dots, vv_{m-1}\}$ and X be the component that contains v in $T - \{w, v_m\}$. Now we consider $f_W(w), f_W(v), f_W^*(w)$ and $f_W^*(v)$. It is routine to check that

$$f_W(w) = f_{W-v}(w) + f_W(w * v), f_W(v) = f_{W-w}(v) + f_W(w * v).$$

Hence,

$$f_W(w) - f_W(v) = f_{W-v}(w) - f_{W-w}(v) = f_{W-v}(w) - |V_{T_m}| - 1.$$

If v is not a center of T and its parent is w, then there is a proper subtree of the component that contains w in $W - v$, say T', with $T' \cong P_{|V_{T_m}|+1}$. Hence, we have $f_{W-v}(w) > f_{T'}(w) \geqslant |V_{T_m}| + 1$, i.e., $f_W(w) > f_W(v)$. By Lemma 2.4 we have $F(T_0) > F(T)$.

Note that neither w nor v is a leaf of W, hence by a similar discussion as above we also have

$$f_W^*(w) - f_W^*(v) = f_{W-v}^*(w) - f_{W-w}^*(v) = f_{W-v}^*(w) - 1 \geqslant 0,$$

i.e., $f_W^*(w) \geqslant f_W^*(v)$. By Lemma 2.4 we have $F^*(T_0) > F^*(T)$. If $w = u$ is the center of T with $d_T(w) > 2$, then we can also have a proper subtrees of the component that contains w in $W - v$ say T'' with $T'' \cong P_{|V_{T_m}|+1}$. By a similar discussion as above, we can also have $F(T_0) > F(T), F^*(T_0) > F^*(T)$. This completes the proof. ☐

4. Enumeration of subtrees of some types of trees

In this section, we determine sharp upper (or lower) bound on the total number of subtrees (or leaf containing subtrees) of some type of trees.

The *matching number* of a graph G is the maximum size of an independent (pair-wise nonincident) set of edges of G and will be denoted by $q(G)$. Let $\mathscr{M}_{n,q}$ be the set of all n-vertex trees with matching number q. Let $A(n,q)$ be the tree that is obtained by attaching $q-1$ pendant edges to $q-1$ pendant vertices of the star $K_{1,n-q}$. It is routine to check that $A(n,q) \in \mathscr{M}_{n,q}$. Given a vertex w in G, call w a *perfectly matched vertex* if it is matched in any maximum matching of G.

Theorem 4.1. *Among $\mathscr{M}_{n,q}$ precisely the graph $A(n,q)$, which has $2^{n-2q+1} \cdot 3^{q-1} + n + q - 2$ subtrees, maximizes the total number of subtrees and has $2^{n-2q+1} \cdot 3^{q-1} - 2^{q-1} + n - 1$ leaf containing subtrees, maximizes the total number of leaf containing subtrees.*

Proof. Choose T in $\mathscr{M}_{n,q}$ such that its total number of subtrees (resp. leaf containing subtrees) is as large as possible. If T contains a pendant path of length $p > 2$, say $v_1v_2v_3 \ldots v_pv$ with $v_1 \in PV(T)$ and $d_T(v) \geqslant 3$, then $f_{T-v_2-v_1}(v_3) < f_{T-v_2-v_1}(v_4)$, $f^*_{T-v_2-v_1}(v_3) < f^*_{T-v_2-v_1}(v_4)$ by Lemma 2.7. Let

$$T_0 = T - v_2v_3 + v_2v.$$

It is routine to check that T_0 is in $\mathscr{M}_{n,q}$. By Lemma 2.4 we get $F(T) < F(T_0), F^*(T) < F^*(T_0)$, a contradiction. Hence, any pendant path contained in T is of length at most 2.

If there exists a non-center vertex $v \in V_T$ such that T contains r pendant edges and s pendant paths of length 2 attached to v, then assume that w is the parent of v. Consider the following possible cases.

- $s = 0$ and w is perfectly matched. Apply C-transformation at v once, and get $r-1$ pendant edges and one pendant path P_3 attached at w in the resultant graph, say $\hat{T}$. It is routine to check that $\hat{T}$ is in $\mathscr{M}_{n,q}$. By Lemma 3.3 we get $F(T) < F(\hat{T}), F^*(T) < F^*(\hat{T})$, a contradiction.

- $s = 0$ and w is not perfectly matched. Applying B-transformation at the edge wv, we get $r+1$ pendant edges at w in the resultant graph, say $\hat{T}$. It is routine to check that $\hat{T}$ is in $\mathscr{M}_{n,q}$. By Lemma 3.2 we get $F(T) < F(\hat{T}), F^*(T) < F^*(\hat{T})$, a contradiction.

- $r = 0$. Applying C-transformation at v, we get $s-1$ pendant paths P_3's and one pendant path P_4 attached at w in the resultant graph, say $\hat{T}$. It is routine to check that $\hat{T}$ is in $\mathscr{M}_{n,q}$. By Lemma 3.3 we get $F(T) < F(\hat{T}), F^*(T) < F^*(\hat{T})$, a contradiction.

- $r > 0, s > 0$ and w is perfectly matched. Applying C-transformation at v, we get $r-1$ pendant edges and $s+1$ pendant paths P_3's attached at w in the resultant graph, say $\hat{T}$. It is routine to check that $\hat{T}$ is in $\mathscr{M}_{n,q}$. By Lemma 3.3 we get $F(T) < F(\hat{T}), F^*(T) < F^*(\hat{T})$, a contradiction.

- $r > 0, s > 0$ and w is not perfectly matched. Applying B-transformation at the edge wv, we get $r+1$ pendant edges and s pendant paths P_3's attached at w in the resultant graph, say $\hat{T}$. It is routine to check that $\hat{T}$ is in $\mathscr{M}_{n,q}$. By Lemma 3.2 we get $F(T) < F(\hat{T}), F^*(T) < F^*(\hat{T})$, a contradiction.

Hence, all the pendant paths of length at most 2 are attached only to the centers of T. In order to characterize the structure of T, it suffices to show that T contains just one center whose degree is larger than 2. Otherwise, assume that T contains two centers, say c_1, c_2, with $d_T(c_1) > 2$ and $d_T(c_2) > 2$. ApplyC'-transformation on c_1

in T to get a new tree, say T'. It's routine to check that T' is in $\mathscr{M}_{n,q}$. By Lemma 3.3, we get $F(T') > F(T)$ and $F^*(T') > F(T)$, a contradiction.

Therefore, we get that $T \cong A(n,q)$ with the center c. Note that in $A(n,q)$ there exist $n-2q+1$ pendant edges and $q-1$ pendant paths of length 2 attached to c, hence

$$\begin{aligned} f_{A(n,q)}(c) &= 2^{n-2q+1} \cdot 3^{q-1}, \\ F(A(n,q)-c) &= F((n-2q+1)P_1 \cup (q-1)P_2) = n-2q+1+3(q-1) = n+q-2, \end{aligned}$$

and

$$F^*(A(n,q)) = F(A(n,q)) - F(A(n,q) - PV(A(n,q))) = F(A(n,q)) - F(K_{1,q-1}).$$

This gives

$$F(A(n,q)) = f_{A(n,q)}(c) + F(A(n,q)-c) = 2^{n-2q+1} \cdot 3^{q-1} + n + q - 2$$

and

$$F^*(A(n,q)) = 2^{n-2q+1} \cdot 3^{q-1} + n + q - 2 - (2^{q-1} + q - 1) = 2^{n-2q+1} \cdot 3^{q-1} - 2^{q-1} + n - 1,$$

as desired. □

Let $\mathscr{S}(n,\gamma)$ be the set of n-vertex trees with domination number γ.

Theorem 4.2. *Among $\mathscr{S}(n,\gamma)$, the tree $A(n,\gamma)$ maximizes the total number of subtrees (resp. leaf containing subtrees).*

Proof. It is known from [21] that $\gamma(G) \leqslant q(G)$, where $q(G)$ is the matching number of G. In order to complete the proof, it suffices to show the following claim.

Claim 1. *If $T_0 \in \mathscr{S}(n,\gamma)$ maximizes the total number of subtrees (resp. leaf containing subtrees), then we have $\gamma(T_0) = q(T_0)$.*

Proof. It suffices to show that $\gamma(T_0) \geqslant q(T_0)$. Otherwise, by the definition of the set $\mathscr{T}(n,\gamma)$, we have $q(T_0) > \gamma(T_0) = \gamma$. Assume that $S = \{v_1, v_2, \ldots, v_\gamma\}$ is a dominating set with cardinality γ. Then there exist γ independent edges $v_1v_1', v_2v_2', \ldots, v_\gamma v_\gamma'$ in T_0. Note that $q(T_0) > \gamma(T_0) = \gamma$, there must exist another edge, say w_1w_2, which is independent of each of edges $v_iv_i',\ i = 1, 2, \ldots, \gamma$.

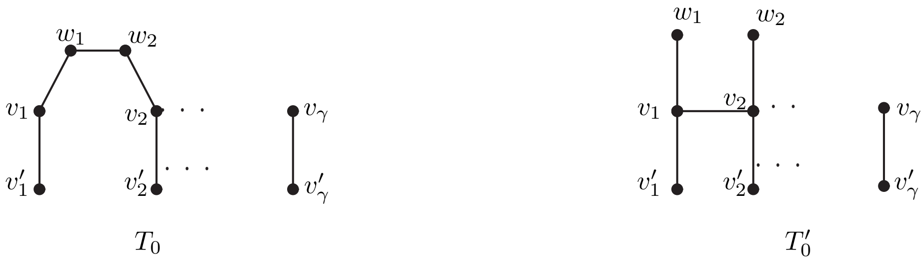

Figure 6: The structures of T_0 and T_0' in Claim 1

If the two vertices w_1, w_2 is dominated by the same vertex $v_i \in S$, then a triangle $C_3 = w_1w_2v_i$ occurs. This is impossible because of the fact that T_0 is a tree. Therefore w_1, w_2 are dominated by two different vertices from S. Without loss of generality, assume that w_i is dominated by the vertex v_i for $i = 1, 2$ (see Fig. 6). Now we construct a new tree $T_0' \in \mathscr{T}(n,\gamma)$ by B-transformation of T_0 on the edges v_1w_1 and v_2w_2, respectively. By Lemma 3.2, we have $F(T_0) < F(T_0')$, $F^*(T_0) < F^*(T_0')$, a contradiction. This completes the proof of Claim 1. $\square$

Theorem 4.2 follows immediately from Theorem 4.1 and Claim 1. $\square$

Let $H \circ K_1$ be the graph obtained by attaching a leaf to each of the vertices of the graph H.

Theorem 4.3. *Let* $T \in \mathscr{S}(n, \frac{n}{2}) (n \geqslant 4)$*, then*

$$F(T) \geqslant 2^{\frac{n}{2}+2} - \frac{n}{2} - 4, \qquad F^*(T) \geqslant 2^{\frac{n}{2}+2} - \frac{n}{2} - 4 - \binom{\frac{n}{2}+1}{2}. \tag{4.1}$$

Each of the equalities in (4.1) holds if and only if $T \cong P_{\frac{n}{2}} \circ K_1$.

Proof. It is known [3, 20] that if $n = 2\gamma$, then a tree T belongs to $\mathscr{S}(n,\gamma)$ if and only if there exists a tree H of order $\gamma = \frac{n}{2}$ such that $T = H \circ K_1$. Hence it suffices to show the following fact.

Fact 2. *For any tree* T*, one has*

$$F(T \circ K_1) \geqslant F(P_{|V_T|} \circ K_1), \quad F^*(T \circ K_1) \geqslant F^*(P_{|V_T|} \circ K_1). \tag{4.2}$$

Each of the equalities in (4.2) holds if and only if $T \cong P_{|V_T|}$.

Proof. For any u in V_T and $1 \leqslant m \leqslant |V_T|$, let $\mathscr{S}^m(T;u)$ denote the set of all m-vertex subtrees of a tree T each of which contains u. It is routine to check that

$$\begin{aligned} F(T \circ K_1) &= \sum_{T_1 \in \mathscr{S}(T)} 2^{|V_{T_1}|} + |V_T| &(4.3)\\ &= \sum_{T_1 \in \mathscr{S}(T-u)} 2^{|V_{T_1}|} + \sum_{T_1 \in \mathscr{S}(T;u)} 2^{|V_{T_1}|} + |V_T| \\ &= \sum_{T_1 \in \mathscr{S}(T-u)} 2^{|V_{T_1}|} + \sum_{m=1}^{|V_T|} |\mathscr{S}^m(T;u)| 2^m + |V_T| &(4.4) \end{aligned}$$

and

$$\begin{aligned} F^*(T \circ K_1) &= F(T \circ K_1) - F(T) \\ &= \sum_{T_1 \in \mathscr{S}(T)} (2^{|V_{T_1}|} - 1) + |V_T| &(4.5)\\ &= \sum_{T_1 \in \mathscr{S}(T-u)} (2^{|V_{T_1}|} - 1) + \sum_{m=1}^{|V_T|} |\mathscr{S}^m(T;u)|(2^m - 1) + |V_T|. &(4.6) \end{aligned}$$

Assume that $T \ncong P_{|V_T|}$. If $|V_T| = 2$ or 3, our result is clearly true. If $|V_T| = 4$, there exist only two trees, i.e., P_4 and $K_{1,3}$, hence $T = K_{1,3}$. In this case, for any $u \in PV(T)$ we have

$$|\mathscr{S}^1(T;u)| = |\mathscr{S}^2(T;u)| = |\mathscr{S}^4(T;u)| = 1, |\mathscr{S}^3(T;u)| = 2 \tag{4.7}$$

And for any $v \in PV(P_4)$, we have

$$|\mathscr{S}^1(P_4;v)| = |\mathscr{S}^2(P_4;v)| = |\mathscr{S}^3(P_4;v)| = |\mathscr{S}^4(P_4;u)| = 1. \tag{4.8}$$

Note that $P_4 - u = K_{1,3} - v$, hence by (4.4), (4.6)-(4.8) we have

$$F(K_{1,3} \circ K_1) > F(P_4 \circ K_1), F^*(K_{1,3} \circ K_1) > F^*(P_4 \circ K_1).$$

In what follows we assume that the inequalities hold in (4.2) for all trees of order less than $|V_T|$. On the one hand, for any $u \in PV(T)$ and $v \in PV(P_{|V_T|})$, we have

$$F((T-u) \circ K_1) \geqslant F((P_{|V_T|} - v) \circ K_1), F^*((T-u) \circ K_1) \geqslant F^*((P_{|V_T|} - v) \circ K_1), \tag{4.9}$$

Each of the equalities in (4.9) holds if and only if $T - u \cong P_{|V_T|} - v$. Hence by (4.3) and (4.5), we have

$$\sum_{T_1 \in \mathscr{S}(T-u)} 2^{|V_{T_1}|} \geqslant \sum_{T_1 \in \mathscr{S}(P_{|V_T|}-v)} 2^{|V_{T_1}|}, \sum_{T_1 \in \mathscr{S}(T-u)} (2^{|V_{T_1}|} - 1) \geqslant \sum_{T_1 \in \mathscr{S}(P_{|V_T|}-v)} (2^{|V_{T_1}|} - 1). \tag{4.10}$$

On the other hand, it is easy to see that for any $w \in PV(T) \setminus \{u\}$, $T - w \in \mathscr{S}^{|V_T|-1}(T; u)$, so we have

$$|\mathscr{S}^{|V_T|-1}(T; u)| > 1 = |\mathscr{S}^{|V_T|-1}(P_{|V_T|}; v)|. \tag{4.11}$$

Furthermore, for $m = 1, 2, \ldots, |V_T| - 2, |V_T|$,

$$|\mathscr{S}^m(T; u)| \geqslant 1 = |\mathscr{S}^m(P_{|V_T|}; v)|. \tag{4.12}$$

Hence, (4.2) follows by (4.4),(4.6),(4.10)-(4.12). This completes the proof of Fact 1. □

Note that $|\mathscr{S}^m(P_n; v)| = 1$ for $m = 1, 2 \ldots, n$, hence by (4.3) and (4.4) we get

$$F(P_n \circ K_1) = \sum_{T_1 \in \mathscr{S}(P_{n-1})} 2^{|V_{T_1}|} + \sum_{m=1}^{n} 2^m + n = F(P_{n-1} \circ K_1) + 2^{n+1} - 1.$$

Hence we have

$$F(P_n \circ K_1) = F(P_1 \circ K_1) + \sum_{i=3}^{n+1} 2^i - (n-1) = 3 + \sum_{i=3}^{n+1} 2^i - (n-1) = 2^{n+2} - n - 4. (n \geqslant 2)$$

and

$$F^*(P_n \circ K_1) = F(P_n \circ K_1) - F(P_n) = 2^{n+2} - n - 4 - \binom{n+1}{2} (n \geqslant 2).$$

This completes the proof. □

Let $P_k(1^a, 1^b)$ be a tree obtained by attaching a and b pendant vertices to the two endvertices of P_k, respectively.

Theorem 4.4. *Let $T \in \mathscr{S}(n, 2)$ with $n \geqslant 6$, then*

$$\begin{aligned} F(T) &\geqslant 3 \cdot \left(2^{\lfloor \frac{n-4}{2} \rfloor} + 2^{\lceil \frac{n-4}{2} \rceil}\right) + 2^{n-4} + n - 1, & (4.13) \\ F^*(T) &\geqslant 3 \cdot \left(2^{\lfloor \frac{n-4}{2} \rfloor} + 2^{\lceil \frac{n-4}{2} \rceil}\right) + 2^{n-4} + n - 11. & (4.14) \end{aligned}$$

The equality in (4.13) (resp. (4.14)) holds if and only if $T \cong P_4(1^{\lfloor \frac{n-4}{2} \rfloor}, 1^{\lceil \frac{n-4}{2} \rceil})$.

Proof. When $n = 6$, this theorem holds as $P_6 \in \mathscr{S}(n, 2)$. So we only consider the case when $n \geqslant 7$. Choose $T \in \mathscr{S}(n, 2)$ such that its total number of subtrees (resp. leaf containing subtrees) is as small as possible. Let $S = \{w_1, w_2\}$ be a dominating set of T.

If $d_T(w_1, w_2) = 1$, T must be the form $P_2(1^a, 1^b)$ with $a + b = n - 2$. Without loss of generality, assume that $a \leqslant b$. Note that $T' = P_3(1^a, 1^{b-1}) \in \mathscr{S}(n, 2)$, and by Lemma 3.2 we have $F(T') < F(T), F^*(T') < F^*(T)$, a contradiction. By a similar discussion we can show that $d_{T_1}(w_1, w_2) \neq 2$. We omit the procedure here.

If $d_T(w_1, w_2) \geqslant 4$, then there exists at least one vertex x on $P_T(w_1, w_2)$ x can not be dominated by w_1 or w_2, which implies that $T \notin \mathscr{S}(n, 2)$. Hence we get $d_T(w_1, w_2) = 3$. That is to say, $T \cong P_4(1^a, 1^b)$ with $a + b = n - 4, 1 \leqslant a \leqslant b$. (Note that $P_4(1^0, 1^{n-4}) = P_3(1^1, 1^{n-5})$). Hence, by direct computing we have

$$\begin{aligned} F(P_4(1^a, 1^b)) &= 3 \cdot (2^a + 2^b) + 2^{n-4} + n - 4 + \binom{3}{2} = 3 \cdot (2^a + 2^b) + 2^{n-4} + n - 1, \\ F^*(P_4(1^a, 1^b)) &= F(P_4(a, b)) - F(P_4) = 3 \cdot (2^a + 2^b) + 2^{n-4} + n - 11. \end{aligned}$$

Note that when $a = b - 1, b$, our results hold immediately. Hence, we consider $a \leqslant b - 2$ in what follows. It is routine to check that

$$2^a + 2^b > 2^{a+1} + 2^{b-1} > \cdots > 2^{\lfloor \frac{n-4}{2} \rfloor} + 2^{\lceil \frac{n-4}{2} \rceil}.$$

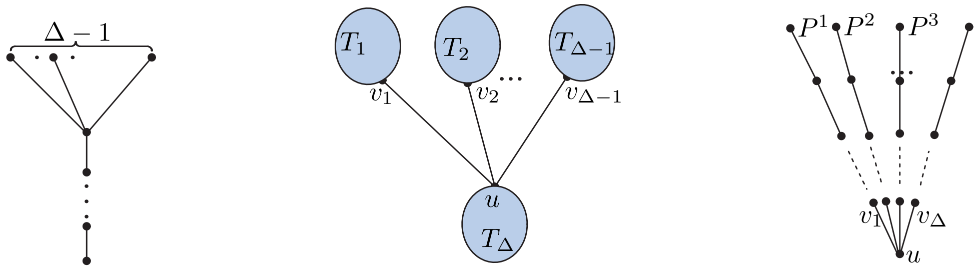
Hence we have

$$\begin{aligned} &F(P_4(1^a, 1^b)) > F(P_4(1^{a+1}, 1^{b-1})) > \cdots > F(P_4(1^{\lfloor \frac{n-4}{2} \rfloor}, 1^{\lceil \frac{n-4}{2} \rceil})), \\ &F^*(P_4(1^a, 1^b)) > F^*(P_4(1^{a+1}, 1^{b-1})) > \cdots > F^*(P_4(1^{\lfloor \frac{n-4}{2} \rfloor}, 1^{\lceil \frac{n-4}{2} \rceil})). \end{aligned}$$

This completes the proof. □

Theorem 4.5. *Let Δ be a positive integer more than two, and let T be an n-vertex tree with maximum degree at least Δ. Then $F^*(T) \geqslant (n - \Delta + 1) \cdot 2^{\Delta - 1} + \Delta - 1$. The equality holds if and only if $T \cong T_{n,\Delta}$, where $T_{n,\Delta}$ is obtained from $P_{n-\Delta+1}$ by attaching $\Delta - 1$ pendant vertices to one endvertex of $P_{n-\Delta+1}$; see Fig. 7(a).*

Proof. Choose an n-vertex tree T with maximum degree at least Δ such that its total number of leaf containing subtrees is as small as possible. Then there exists a vertex u in V_T such that $d_T(u) \geqslant \Delta$. Without loss of generality, we assume that $\{v_1, v_2, \ldots, v_{\Delta-1}\} \subseteq N_T(u)$. Obviously, the graph $T - \{uv_1, uv_2, \ldots, uv_{\Delta-1}\}$ contains Δ components $T_1, T_2, \ldots, T_{\Delta-1}, T_\Delta$, where T_i contains vertex v_i for $i = 1, 2, \ldots, \Delta - 1$ and T_Δ contains at least two vertices with $u \in V_{T_\Delta}$; see Fig. 7(b).



(a) $T_{n,\Delta}$ (b) T (c) T^*

Figure 7: Trees T, T^* and $T_{n,\Delta}$ in the proof of Theorem 4.5.

Next we are to show that each T_i is a path for $i = 1, 2 \dots, \Delta$. In fact, if there exists an $i \in \{1, 2 \dots, \Delta\}$ such that T_i is not a path. Applying A-transformations of T on T_i to get a tree, say $\hat{T}$. By Lemma 3.1 we have $F^*(\hat{T}) < F^*(T)$, a contradiction. Hence $T \cong T^*$, where T^* is depicted in Fig. 7(c).

Now we show that for any $u_i, u_j \in PV(T)$, $u_iu \in E_T$ or $u_ju \in E_T$. In fact, if there exists two pendant vertices, say u_1, u_2, such that $u_1u, u_2u \notin E_T$. Let $P_T(u_1, u_2) = u_1w_1w_2 \dots w_ru_2$ with $u, v_1, v_2 \in \{w_1, w_2, \dots, w_r\}$ and $u \neq w_1, w_r$. Let $T^{**} = T - \{uv_3, uv_4, \dots, uv_\Delta\} + \{w_1v_3, w_1v_4, \dots, w_1v_\Delta\}$. By Lemma 2.6, $F^*(T^{**}) < F^*(T)$, a contradiction. Hence, $T \cong T_{n,\Delta}$.

Note that $f_{T_{n,\Delta}}(u) = (n - \Delta + 1) \cdot 2^{\Delta - 1}$, $F(T_{n,\Delta} - u) = F((\Delta - 1)P_1 \cup P_{n-\Delta})$ and $F(H(T_{n,\Delta})) = F(T_{n,\Delta} - PV(T_{n,\Delta})) = F(P_{n-\Delta})$, hence we have

$$F(T_{n,\Delta}) = f_{T_{n,\Delta}}(u) + F(T_{n,\Delta} - u) = (n - \Delta + 1) \cdot 2^{\Delta-1} + \Delta - 1 + \binom{n - \Delta + 1}{2}.$$

So we have

$$F^*(T_{n,\Delta}) \quad = \quad F(T_{n,\Delta}) - F(H(T_{n,\Delta})) = (n - \Delta + 1) \cdot 2^{\Delta-1} + \Delta - 1,$$

as desired. $\square$

Theorem 4.6. *Let Δ be a positive integer more than two, and let T be an n-vertex tree with maximum degree at least Δ having a perfect matching. Then*

$$F(T) \quad \geqslant \quad 2(n - 2\Delta + 3) \cdot 3^{\Delta-2} + 3 \cdot \Delta - 5 + \binom{n - 2\Delta + 3}{2}, \tag{4.15}$$

$$F^*(T) \quad \geqslant \quad 2(n - 2\Delta + 3) \cdot 3^{\Delta-2} - (n - 2\Delta + 2) \cdot 2^{\Delta-2} + n - 1. \tag{4.16}$$

Equality holds in (4.15) (resp. (4.16)) if and only if $T \cong T'_{n,\Delta}$, where $T'_{n,\Delta}$ is the tree obtained from $P_{n-2\Delta+1}$ by attaching $(\Delta - 2)$ P_3's and one P_2 to one endvertex of $P_{n-2\Delta+3}$; see Fig. 8.

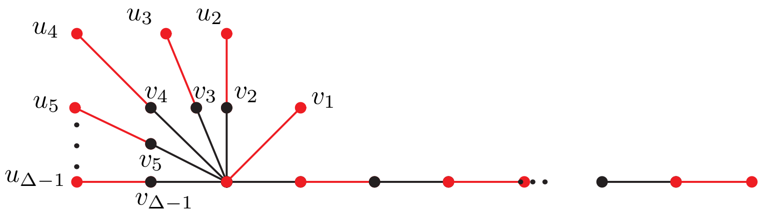


Figure 8: Tree $T'_{n,\Delta}$.

Proof. Choose an n-vertex tree T with maximum degree at least Δ having a perfect matching such that its total number of subtree (resp. leaf containing subtrees) is as small as possible. By a similar discussion as in the proof of Theorem 4.5, we can obtain that T is the graph depicted in Fig. 7(b).

Note that for any two n-vertex tree T_1 and T_2, if T_2 is an A-transformation of T_1, then the maximum matching number of T_2 is no less than that of T_1. Hence, by a similar discussion as in Theorem 4.5, we have $T \cong T^*$ as depicted in Fig. 7(c) and T^* contains a perfect matching, say M. Note that for the vertex u in T^*, u is saturated by M, hence without loss of generality we assume that $uv_1 \in M$. Then we have $|V_{T_1}|, |V_{T_\Delta}|$ are odd and $|V_{T_2}|, \dots |V_{T_{\Delta-1}}|$ are even.

Next we show that $v_1 \in PV(T) = \{u_1, u_2 \dots u_\Delta\}$. Suppose that $P_T(u_1, u_\Delta) = u_1 w_1 w_2 \dots w_r u_\Delta$ with $u, v_1, v_\Delta \in \{w_1, w_2 \dots, w_r\}$ and $u \neq w_1, w_r$. Let $\hat{T} = T - \{uv_2, uv_3, \dots, uv_{\Delta-1}\} + \{w_1v_2, w_1v_3, \dots, w_1v_{\Delta-1}\}$, M is also a perfect matching of $\hat{T}$. By Lemma 2.6, we have $F(T) > F(\hat{T}), F^*(T) > F^*(\hat{T})$, a contradiction. Hence we have $v_1 \in PV(T)$. For convenience, let $u_1 := v_1$.

Now we show that for any $u_i, u_j \in PV(T) \setminus \{u_1\}$, $d_T(u_i, u) = 2$ or $d_T(u_j, u) = 2$. Note that T contains a perfect matching, hence $d_T(u_i, u) \geqslant 2$ for $u_i \in PV(T) \setminus \{u_1\}$. If there exist two vertices in $PV(T) \setminus \{u_1\}$, say u_2, u_3, such that $d_T(u_2, u) > 2$, $d_T(u_3, u) > 2$. Denote the unique path connecting u_2, u_3 by $P_T(u_2, u_3) = u_2 s_1 s_2 \dots s_{t-1} s_t u_3$ with $u = s_k$, where $k \neq 1, 2, t-1, t$. Let $T^{**} = T - \{uv_1, uv_4, \dots u_\Delta\} + \{s_2v_1, s_2v_4, \dots s_2v_\Delta\}$. Note that $M - uv_1 + s_2v_1$ is a perfect matching of T^{**}. By Lemma 2.6, we have $F(T) > F(T^{**}), F^*(T) > F^*(T^{**})$, a contradiction. So we have $T \cong T'_{n,\Delta}$; see Fig. 8.

Note that $f_{T'_{n,\Delta}}(u) = 2(n - 2\Delta + 3) \cdot 3^{\Delta-2}, F(T'_{n,\Delta} - u) = F((\Delta - 2)P_2 \cup P_1 \cup P_{n-2\Delta+2})$, hence

$$F(T'_{n,\Delta}) = 2(n - 2\Delta + 3) \cdot 3^{\Delta-2} + 3(\Delta - 2) + 1 + \binom{n - 2\Delta + 3}{2}. \tag{4.17}$$

Note that $H(T'_{n,\Delta}) = T'_{n,\Delta} - PV(T'_{n,\Delta}) = T_{n-\Delta,\Delta-1}$. Hence,

$$F(H(T'_{n,\Delta})) = (n - 2\Delta + 2) \cdot 2^{\Delta-2} + \Delta - 2 + \binom{n - 2\Delta + 2}{2}.$$

Together with (4.17) and Fact 1, we have

$$F^*(T'_{n,\Delta}) = F(T'_{n,\Delta}) - F(H(T'_{n,\Delta})) = 2(n - 2\Delta + 3) \cdot 3^{\Delta-2} - (n - 2\Delta + 2) \cdot 2^{\Delta-2} + n - 1,$$

as desired. □

Let $\mathscr{S}_n^k$ be the set of all n-vertex trees with k leaves ($2 \leqslant k \leqslant n-1$). A *spider* is a tree with at most one vertex of degree more than 2, called the *hub* of the spider (if no vertex of degree more than two, then any vertex can be the hub). A *leg* of a spider is a path from the hub to a leaf. Let T_n^k be an n-vertex tree with k legs satisfying all the lengths of k legs, say $l_1, l_2, \dots, l_k$, are almost equal lengths, i.e., $|l_i - l_j| \leqslant 1$ for $1 \leqslant i, j \leqslant k$. It is easy to see that $T_n^k \in \mathscr{S}_n^k$ and $l_i + l_j \in \{2\lfloor \frac{n-1}{k} \rfloor, \lfloor \frac{n-1}{k} \rfloor + \lceil \frac{n-1}{k} \rceil, 2\lceil \frac{n-1}{k} \rceil\}$, where $1 \leqslant i, j \leqslant k$.

Theorem 4.7. *Among $\mathscr{S}_n^k$ with $n \geqslant 2$, precisely the graph T_n^k, has*

$$\left(\left\lfloor \frac{n-1}{k} \right\rfloor + 1\right)^i \left(\left\lceil \frac{n-1}{k} \right\rceil + 1\right)^j - \left(\left\lfloor \frac{n-1}{k} \right\rfloor\right)^i \left(\left\lceil \frac{n-1}{k} \right\rceil\right)^j + i \left\lfloor \frac{n-1}{k} \right\rfloor + j \left\lceil \frac{n-1}{k} \right\rceil$$

leaf containing subtrees, maximizes the total number of leaf containing subtrees, where $i + j = k$ and $n - 1 \equiv j$ (mod k).

Proof. Choose $T \in \mathscr{S}_n^k$ such that its total number of leaf containing subtrees is as large as possible. If $k = 2$ or, $n - 1$, it is easy to see that $\mathscr{S}_n^k = \{T_n^k\}$, our result follows immediately. Hence, in what follows we consider $2 < k < n - 1$. For convenience, let W be the set of vertex of degree larger than 2 in T.

First we show that for any $v \in W$, v is a center of T. Otherwise, apply a C transformation to v of T to get a new tree T'. It's straightforward to check that $T' \in \mathscr{S}_n^k$. By Lemma 3.3, we have $F^*(T) < F^*(T')$, a contradiction to the choice of T. Hence, for any vertex $w \in V_T$ that is not the center of T, we have $d_T(w) \leqslant 2$. If there are two center vertices c_1 and c_2 in W, apply a C'-transformation to c_1 of T to get a new tree T'. Then T' is a spider and by Lemma 3.3 we have $F^*(T') > F^*(T)$, a contradiction.

Now suppose c is the only vertex in W. We are to show that for any $u_i, u_j \in PV(T)$, one has $|d_T(c, u_i) - d_T(c, u_j)| \leqslant 1$. Assume to the contrary that there exist two pendant vertices, say u_t, u_l, in $PV(T)$ such that

$$|d_T(c, u_t) - d_T(c, u_l)| \geqslant 2. \tag{4.18}$$

Denote the unique path connecting u_t and u_l by $P_s = w_1 w_2 \ldots w_{i-1} w_i w_{i+1} \ldots w_s$, where $w_1 = u_t, w_s = u_l$ and $w_i = c, 1 \leqslant i \leqslant s$. In view of (4.18), we have

$$c = w_i \neq w_{\lfloor \frac{s+1}{2} \rfloor} \quad \text{and} \quad c = w_i \neq w_{\lceil \frac{s+1}{2} \rceil}.$$

Hence, by Lemma 2.6 there exists an n-vertex tree $T' \in \mathscr{S}_n^k$ such that $F^*(T) < F^*(T')$, a contradiction to the choice of T. So we have $T \cong T_n^k$. Furthermore, we know from ([8]) that

$$F(T_n^k) = \left(\left\lfloor \frac{n-1}{k} \right\rfloor + 1 \right)^i \left(\left\lceil \frac{n-1}{k} \right\rceil + 1 \right)^j + i \binom{\lfloor \frac{n-1}{k} \rfloor + 1}{2} + j \binom{\lceil \frac{n-1}{k} \rceil + 1}{2}, \tag{4.19}$$

where $i + j = k$ and $n - 1 \equiv j \pmod{k}$.

By Fact 1,

$$F^*(T_n^k) = F(T_n^k) - F(T_n^k - PV(T_n^k)) = F(T_n^k) - F(T_{n-k}^k).$$

Hence in view of (4.19),

$$\begin{aligned} F^*(T_n^k) &= \left(\left\lfloor \frac{n-1}{k} \right\rfloor + 1 \right)^i \left(\left\lceil \frac{n-1}{k} \right\rceil + 1 \right)^j + i \binom{\lfloor \frac{n-1}{k} \rfloor + 1}{2} + j \binom{\lceil \frac{n-1}{k} \rceil + 1}{2} \\ &\quad - \left[\left(\left\lfloor \frac{n-1}{k} \right\rfloor \right)^i \left(\left\lceil \frac{n-1}{k} \right\rceil \right)^j + i \binom{\lfloor \frac{n-1}{k} \rfloor}{2} + j \binom{\lceil \frac{n-1}{k} \rceil}{2} \right] \\ &= \left(\left\lfloor \frac{n-1}{k} \right\rfloor + 1 \right)^i \left(\left\lceil \frac{n-1}{k} \right\rceil + 1 \right)^j - \left(\left\lfloor \frac{n-1}{k} \right\rfloor \right)^i \left(\left\lceil \frac{n-1}{k} \right\rceil \right)^j + i \left\lfloor \frac{n-1}{k} \right\rfloor + j \left\lceil \frac{n-1}{k} \right\rceil, \end{aligned}$$

where $i + j = k$ and $n - 1 \equiv j \pmod{k}$.

This completes the proof. $\square$

Let $\mathscr{S}_{n,d}$ denote the set of all n-vertex trees of diameter d. Let $\hat{T}_{n,k}^d$ be the n-vertex tree obtained from $P_{d+1} = v_1 v_2 \ldots v_d v_{d+1}$ by attaching $n - d - 1$ pendant edges to v_k; see Fig. 9.

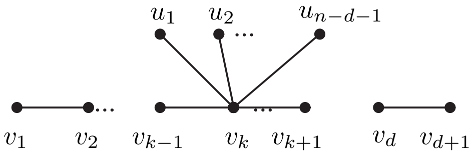

Figure 9: Tree $\hat{T}_{n,k}^d$.

Theorem 4.8. *For any $n \geqslant 2$, precisely the graph $\hat{T}_{n,i}^d$, which has*

$$2^{n-d-1} \left(\left\lfloor \frac{d}{2} \right\rfloor + 1 \right) \left(\left\lceil \frac{d}{2} \right\rceil + 1 \right) + \binom{\lfloor \frac{d}{2} \rfloor + 1}{2} \binom{\lceil \frac{d}{2} \rceil + 1}{2} + n - d - 1 - \binom{d}{2}$$

leaf containing subtrees, minimizes the total number of leaf containing subtrees among $\mathscr{S}_{n,d}$, where $i = \lfloor \frac{d}{2} \rfloor + 1$ or $i = \lceil \frac{d}{2} \rceil + 1$.

Proof. If $T \in \mathscr{S}_{n,d}$, it is easy to see that $|V_{H(T)}| \geqslant d-1$. By Lemma 2.1 we have $F(H) \geqslant F(P_{d-1})$ with equality if and only if $H \cong P_{d-1}$, which is equivalent to that T is a caterpillar tree of diameter d. On the one hand, it is known ([22]) that $F(T) \leqslant F(\hat{T}^d_{n,i})$ with equality if and only if $T \cong \hat{T}^d_{n,i}$, where $i = \lfloor \frac{d}{2} \rfloor + 1$ or $i = \lceil \frac{d}{2} \rceil + 1$. Together with Fact 1, for any $T \in \mathscr{S}_{n,d}$, we have

$$F^*(T) = F(T) - F(H(T)) \leqslant F(\hat{T}^d_{n,i}) - F(P_{d-1}) = F^*(\hat{T}^d_{n,i}) \tag{4.20}$$

with equality if and only if $T \cong \hat{T}^d_{n,i}$ for $i = \lfloor \frac{d}{2} \rfloor + 1$ or $i = \lceil \frac{d}{2} \rceil + 1$. On the other hand, it is known ([8]) that

$$F(\hat{T}^d_{n,i}) = 2^{n-d-1}\left(\left\lfloor \frac{d}{2} \right\rfloor + 1\right)\left(\left\lceil \frac{d}{2} \right\rceil + 1\right) + \binom{\lfloor \frac{d}{2} \rfloor + 1}{2}\binom{\lceil \frac{d}{2} \rceil + 1}{2} + n - d - 1.$$

Together with (4.20), we have

$$F^*(\hat{T}^d_{n,i}) = 2^{n-d-1}\left(\left\lfloor \frac{d}{2} \right\rfloor + 1\right)\left(\left\lceil \frac{d}{2} \right\rceil + 1\right) + \binom{\lfloor \frac{d}{2} \rfloor + 1}{2}\binom{\lceil \frac{d}{2} \rceil + 1}{2} + n - d - 1 - \binom{d}{2}.$$

This completes the proof. □

5. Concluding remarks

Du and Zhou [2] characterized the extremal trees with matching number q that minimize the Wiener index; in this paper we show the counterparts of these results for the total number of subtrees of n-vertex trees with matching number q. In view of Theorem 4.2, we conjecture that there exist the counterparts of these results for the Wiener index among the n-vertex trees with domination number γ. Furthermore, for the Wiener index, sharp upper and lower bounds of trees with given degree sequence are determined; see [17, 23, 24]. It is natural for us to determine sharp upper and lower bounds on the total number of subtrees of trees with given degree sequence. It is difficult but interesting and it is still open. We leave these problems for future study.
